IDENTIFICATION TABLE

Model	Input Power Frequency	Chassis	Cabinet	Speaker
412-H	50-60 Cycles	30346	30589	30602
412-HB	25-60 Cycles	30347	30589	30602

SPECIFICATIONS

Voltage Rating ..... Standard 50-60 Cycles; also available 25-60 Cycles
Type of Circuit ..... Superheterodyne
Tuning Ranges ..... 0.54 to 1.7 Mc.; 2.3 to 7.6 Mc.; 7.6 to 23 Mc.
Number of Tubes ..... Six
Type of Tubes .....
- 1—6A8 Modulator
- 1—6J5 Oscillator
- 1—6K7 I. F. Amplifier
- 1—6B8 Demodulator, A. V. C. and Audio
- 1—6K6G Output
- 1—80 Rectifier

Input Power Rating ..... 65 Watts
Intermediate Frequency ..... 455 Kilocycles
Speaker Voice Coil Impedance at 400 cycles ..... Approximately 5 Ohms
Speaker Field Coil Resistance ..... Approximately 1200 Ohms

ALIGNING INFORMATION

Never Align Unless Absolutely Necessary

Use a good modulated signal generator (test oscillator) with variable output voltage and connect a sensitive output meter across the voice coil of the speaker.

Always align using the smallest possible input from the signal generator. A strong signal makes adjustments inaccurate.

Always have receiver volume control full on. Never align with tone control in "Bass" position. See location chart on Page 1 for location of all the aligning adjustment screws.

Aligning Procedure (follow this order exactly)

I. Dial pointer adjustment.

With the plates of the gang tuning capacitor fully engaged, set the dial pointer directly on the upper black line located at the extreme low frequency end of the dial scale.

II. Intermediate frequency adjustments.

1. Set the range switch to the Standard Broadcast position.
2. Tune set to extreme low frequency end of the dial.
3. Connect the ground terminal of the signal generator to the ground terminal of the chassis.
4. Introduce a modulated signal of 455 Kilocycles to the grid cap of the 6A8 Tube, using a 0.1 microfarad capacitor in series with the output lead of the signal generator. (Do not remove the grid clip from this tube.)
5. Adjust the I. F. Aligners for maximum signal in the following order:
   A. Secondary of second I. F. transformer.
   B. Primary of second I. F. transformer.
   C. Secondary of first I. F. transformer.
   D. Primary of first I. F. transformer.

III. Radio frequency adjustments.

Short Wave Range (C Band)

1. Replace the 0.1 microfarad capacitor in series with the output lead of the signal generator with a 400 ohm carbon type resistor, and connect it to the antenna terminal of the chassis.
2. Set the range switch to the short-wave position (C Band).
3. Set the signal generator frequency and the receiver tuning dial to 8 megacycles.
4. Adjust the "8 MC." OSCillator and ANTenna aligners (iron cores) for maximum signal.
5. Set the signal generator frequency and the receiver tuning dial to 20 megacycles.
6. Adjust the "20 MC." OSCillator (air trimmer) aligner by loosening the lock nut and moving the plunger in or out until maximum signal is obtained. If two positions are found at which maximum signal occurs always use the minimum capacitance position (most outward position of plunger). Always be sure to tighten the lock nut after the aligning adjustment has been completed. An SD-76 aligning tool is recommended for alignment of air trimmer capacitors of the plunger type.
7. Adjust the "20 MC." ANTenna aligning capacitor for maximum signal.
8. Repeat operations 3, 4, 5, 6 and 7 until no further improvement results.

Medium Wave Range (B Band).

Leave the receiver connected to the signal generator in the same manner as when adjusting the Short Wave Range (C Band).

1. Set the range switch to the Medium short-wave position.
2. Set the signal generator frequency and the receiver tuning dial to 2.5 megacycles.
3. Adjust the "2.5 MC." OSCillator and ANTenna aligners (iron cores) for maximum signal.

4. Set the signal generator frequency and the receiver tuning dial to 7 MC.
5. Adjust the "7 MC." OSCillator and ANTenna aligning capacitors for maximum signal.
6. Repeat operations 2, 3, 4 and 5 until no further improvement results.

Standard Broadcast Range (A Band).

1. Replace the 400 ohm carbon type resistor in series with the output lead from the signal generator with a 200 micro-microfarad capacitor.
2. Set the range switch to the Standard Broadcast position.
3. Set the signal generator frequency and the receiver tuning dial to 0.6 MC.
4. Adjust the "0.6 MC." OSCillator, Bi-Resonator and ANTenna aligners (iron cores) for maximum signal.
5. Set the signal generator frequency and the receiver tuning dial to 1.5 MC.
6. Adjust the "1.5 MC." OSCillator, Bi-Resonator and ANTenna aligning capacitors for maximum signal.
7. Repeat operations 3, 4, 5 and 6 until no further improvement results.

CONTINUITY TEST

CAUTION: Remove all tubes and disconnect the receiver from the power supply and short C2 (16 mf. capacitor) to chassis base before making continuity test. Be sure to remove the "short" after continuity tests have been completed.

Use a good meter capable of measuring accurately up to several megohms.

The resistances given are often approximate, owing to electrolytic capacitors in the circuit. When this is the case, be sure to reverse the test leads and read the highest resistance.

Read from the indicated terminals to chassis base unless otherwise specified.

See location chart on Page 2 for position and numbering of terminals.

NORMAL VOLTAGE READINGS

Take all readings with chassis operating and tuned to approximately 1000 Kc.—no signal.
Use a line voltage of 120 volts, or make allowance for any slight variation.
Use a good high resistance voltmeter having a resistance of at least 1000 ohms per volt.
Take all D. C. readings on the 500 volt scale except when an asterisk appears.
Read from indicated terminals to chassis base.
See location chart on Page 1 for position of terminals.
A. C. voltages are indicated by italics.
